Lecture 4: Persistence

Olivier Liechti TWEB

Haute Ecole d'Ingénierie et de Gestion du Canton de Vaud

Today's agenda

14h00 - 15h00	60'	JavaScript 101 reminders Prototypes and .prototype Lecture/exercise Consuming a REST API, coordination asynchronous operations
15h00 - 15h10	10'	Break
15h10 - 16h25	75'	JavaScript 101: asynchronous programming async.js, promises Lecture: MongoDB Data modeling, CRUD operations, drivers

On what objects can I find a "prototype" property and why is it useful?

#1 most objects do NOT have prototype property

```
var student = { "name" : "john doe"};
console.log(student.protoype); // undefined
```

#2 to find the prototype of an object, use Object.getPrototypeOf

```
var father = {};
var son = Object.create(father);
var proto = Object.getPrototypeOf(son);
console.log ( proto === father); // true
```

#3 all functions have a prototype property

```
function f() {};
console.log(f.prototype); // "{}"
```

#4 if an object **o** is created with "new **f**()", then the prototype of **o** is **f.prototype**.

```
function Student() {};
var s = new Student();
console.log( Object.getPrototypeOf(s) ===
Student.prototype); // true
```

#5 we use this feature to share code between object instances

```
function Student() {};
Student.prototype.study = function() {};

var s1 = new Student();
var s2 = new Student();
s1.study(); // s1 inherits study from its proto
s2.study(); // same thing for s2

console.log( s1.study === s2.study ); // true
```

Haute Ecole d'Ingénierie et de Gestion du Canton de Vaud

Let's celebrate October!

Phase 1

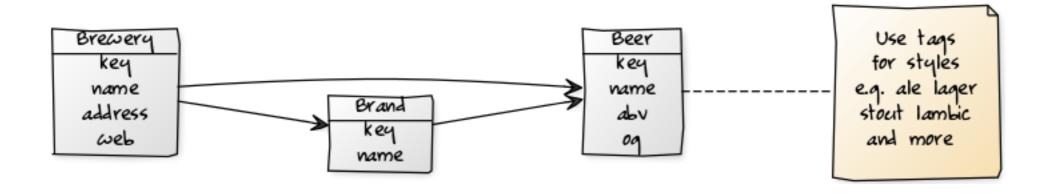

- beer.db is a free and open beer data project
- http://openbeer.github.io/
- Web UI: http://prost.herokuapp.com
- REST API: http://prost.herokuapp.com/api/v1

{
 key: "dedollearabier",
 title: "De Dolle Arabier",
 synonyms: null,
 abv: "8.0",
 srm: null,
 og: null,
 - tags: [
 "blond",
 "belgian strong pale ale"
],
 brewery: {
 key: "dedollebrouwers",
 title: "De Dolle Brouwers"
 },
 - country: {
 key: "be",
 title: "Belgium"
 }
}

http://prost.herokuapp.com/api/v1/beer/rand

 Can we write a Node.js script (command line utility) which fetches 100 random beers and stores them in local files?

- Can we write a Node.js script (command line utility) which fetches 100 random beers and stores them in local files?
 - How do we setup the project, knowing that we will need to use npm modules?
 - How do we invoke the REST API endpoint and fetch a JSON beer?
 - How do we store one beer in a file?
 - How do we execute these operations in sequence?
 - How do we fetch 10 beers and know that we are done?

 How do we setup the project, knowing that we will need to use npm modules?

mkdir okto cd okto

This will create a package.json file for your project

npm init

```
Use `npm install <pkg> --save` afterwards to install a package and
save it as a dependency in the package.json file.
Press ^C at any time to quit.
name: (okto)
version: (1.0.0) 0.1.0
description: A beer utility
entry point: (index.js) okto.js
test command:
git repository:

```

- How do we invoke the REST API endpoint and fetch a JSON beer?
 - If you browse through the Node.js documentation, you will find a module named **http**, with a **httpRequest()** function.
 - Third-party developers have developed more powerful http client libraries and have shared them on npm.
 - request (https://www.npmjs.com/package/request) has been downloaded 12,370,637 times in the last month.

npm install --save request

```
$ ls -l
total 8
drwxr-xr-x 3 admin staff 102 7 oct 14:52 node_modules
-rw-r--r-- 1 admin staff 278 7 oct 14:52 package.json
```

How do we invoke the REST API endpoint and fetch a JSON beer?

```
touch okto.js // and then use your favorite editor...
```

```
var request = require('request');

var BEER_API_ENDPOINT = "http://prost.herokuapp.com/api/v1/beer/rand";

request(BEER_API_ENDPOINT, function (error, response, body) {
   if (!error && response.statusCode == 200) {
      console.log("We have received a response from the BEER API.");
      console.log(body);
   } else {
      console.log("Could not get a response from the BEER API: " + error);
   }
   });
      This is a string... we would prefer a JavaScript object
```

```
$ node okto.js
We have received a response from the BEER API.
{"key":"unertlweissbier","title":"Unertl Wei\u00dfbier","synonyms":null,"abv":null,"srm":null,"og":null,"tags":
[],"brewery":{},"country":{"key":"de","title":"Germany"}}
```

 We can define default parameters for all of our HTTP requests. We can specify that in general, we expect JSON and that the response should be automatically parsed.

```
var request = require('request');
var BEER API ENDPOINT = "http://prost.herokuapp.com/api/v1/beer/rand";
restClient = request.defaults( { json: true, timeout: 2000 } );
restClient.get(BEER API ENDPOINT, function (error, response, body) {
  if (!error && response.statusCode == 200) {
    console.log("We have received a response from the BEER API.");
    console.log(body); console.log(body.title);
  } else {
     console.log("Could not get a response from the BEER API: " + error);
});
            We have received a response from the BEER API.
            { key: 'ozenoyukidokeipa',
              title: 'Ozeno Yukidoke IPA',
                                                                 This is now a JavaScript
              synonyms: null,
              abv: '5.0',
                                                                object and it is possible to
              srm: null,
              og: null,
                                                                   access its properties
              tags: [],
              brewery: {},
              country: { key: 'jp', title: 'Japan' } }
            Ozeno Yukidoke IPA
```

- How do we store one beer in a file?
- We can use the standard fs Node.js module.

```
var fs = require('fs');

function saveBeerInFile( beer ) {
    var filename = beer.key + ".json";
    fs.writeFile(filename, JSON.stringify(beer), function (err) {
        if (err) throw err;
        console.log('Beer has been saved in ' + filename);
    });
}

var beer = {
    "key" : "testBeer",
    "title" : "just a test"
}
saveBeerInFile( beer );
Let's validate this step independently from the
HTTP request!
```

```
$ node okto.js
Beer has been saved in testBeer.json
$ more testBeer.json
{"key":"testBeer","title":"just a test"}
```

How do we fetch 10 beers and know that we are done?

```
console.log("Before the loop");
for (var i=0; i<10; i++) {
    fetchBeer(function(err, beer) {
        if (err) {
            console.log("Could not fetch a beer, nothing we can do...");
        } else {
            saveBeerInFile(beer);
        }
    });
}
console.log("After the loop");</pre>
```

```
$ mkdir beers
$ node okto.js
                                                                          This is an asynchronous
Before the loop
After the loop
                                                                        process, so we have failed!
Beer has been saved in beers/redoakframboisefroment.json

```

Let's use a progress monitor to keep track of our progress.

```
function createProgressMonitor(numberOfOperationsToPerform, callback) {
     var numberOfSuccessfulOperations = 0;
     var numberOfFailedOperations = 0;
     function checkIfDone() {
          if (numberOfSuccessfulOperations + numberOfFailedOperations >= numberOfOperationsToPerform) {
               console.log("Progress monitor has detected that all operations have been completed.");
               callback(null, {
                                                             Here, we create two functions. So 2
                    successes: numberOfSuccessfulOperations,
                    failures: numberOfFailedOperations
                                                                closures are formed. The two
               });
                                                             function objects will keep access to
                                                                    the following variables:
     };
     return {
                                                             numberOfOperationsToPerform
          reportSuccess: function() {
               numberOfSuccessfulOperations+
                                                             numberOfSuccessfulOperations
               checkIfDone();
                                                                numberOfFailedOperations
          reportFailure: function() {
               numberOfFailedOperations++;
                                                                The variables are private and
               checkIfDone();
                                                            cannot be accessed directly from the
          We return an object, which gives us access
                                                             code calling createProgressMonitor.
                        to two functions.
```

Let's use a progress monitor to keep track of our progress.

```
When we detect that we are
                                                                          done with all operations, we
function createProgressMonitor(numberOfOperationsToPerform, callback) {
     var numberOfSuccessfulOperations = 0;
                                                                            will invoke this callback
     var numberOfFailedOperations = 0;
                                                                             provided by the client
     function checkIfDone() {
          if (numberOfSuccessfulOperations + numberOfFailedOperations >= numberOfOperationsToPerform) {
               console.log("Progress monitor has detected that all operations have been completed.");
               callback(null, {
                    successes: numberOfSuccessfulOperations,
                    failures: numberOfFailedOperations
               });
     };
                                                               When we invoke the callback,
     return {
          reportSuccess: function() {
                                                                 we provide the number of
               numberOfSuccessfulOperations++;
                                                              successful and failed operations.
               checkIfDone();
          reportFailure: function() {
               numberOfFailedOperations++;
               checkIfDone();
     };
```

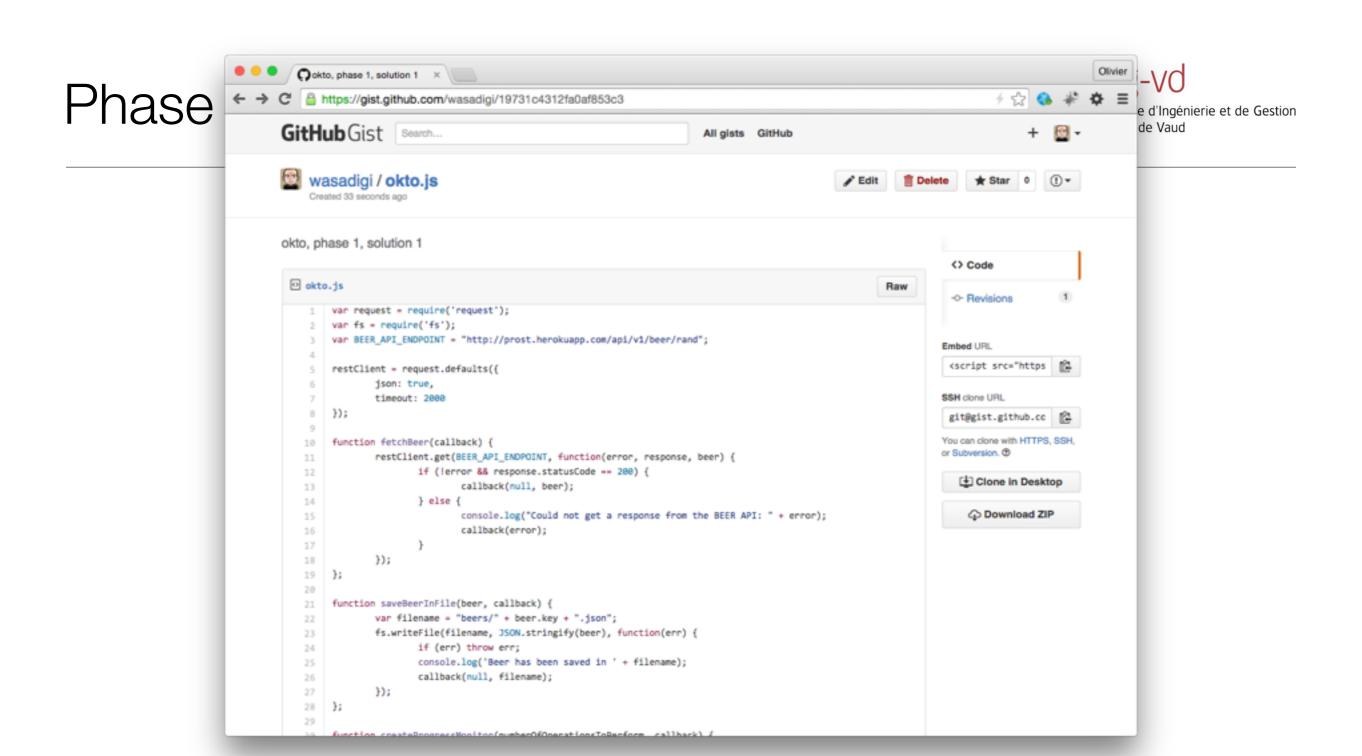

And now, let's use the progress monitor!

This will be called when we are completely done.

```
var numberOfBeersToFetch = 100;
var progressMonitor = createProgressMonitor(numberOfBeersToFetch, function( err, results) {
     console.log("Now, we know that all operations have completed.");
     console.log(results.successes + " beers have bee successfully fetched and saved.");
     console.log(results.failures + " beers have not been fetched or saved.");
});
                                                                    We launch the 100
for (var i = 0; i < numberOfBeersToFetch; i++) {</pre>
                                                                asynchronous operations
     fetchBeer(function(err, beer) {
          if (err) {
               console.log("Could not fetch a beer, nothing we can do...");
               progressMonitor.reportFailure();
          } else {
                                                                      We need to inform the progress
               saveBeerInFile(beer, function(err) {
                                                                       monitor about the outcome of
                     if (err) {
                          progressMonitor.reportFailure();
                                                                               the operations
                     } else {
                          progressMonitor.reportSuccess();
               });
     });
```

```
$ node okto.js
Beer has been saved in beers/santafe.json
Beer has been saved in beers/tipopils.json
Beer has been saved in beers/seasonalhell.json
                                                     The API call has timed out!

Could not get a response from the BEER API: Error: ETIMEDOUT
Could not fetch a beer, nothing we can do...
Progress monitor has detected that all operations have been completed.
Now, we know that all operations have completed.
99 beers have bee successfully fetched and saved.
1 beers have not been fetched or saved.
```

https://gist.github.com/wasadigi/ 19731c4312fa0af853c3

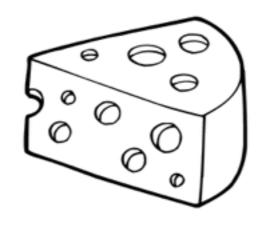

How can I execute multiple asynchronous operations in sequence?

- The principle of passing a callback function when invoking an asynchronous operation is pretty straightforward.
- Things get more tricky as soon as you want to coordinate multiple tasks. Consider this simple example...

First get milk...

... then make cheese...

... then sell it.

Let's prepare the individual tasks...

```
function milkCow( callbackWhenMilkIsAvailable ) {
   console.log("Start to milk cow...");
   setTimeout( function() {
      console.log("Done milking cow.");
      callbackWhenMilkIsAvailable(null, "MILK");
   }, 5000);
};
```

The first parameter is the **error** (if one happened) and the second one is the **result**.

Instead of calling this parameter "callback" or "cb" (like most developers), I like to use explicit names. It makes code easier to read, especially when you have nested functions.

```
function prepareCheese( milk, callbackWhenCheeseIsAvailable ) {
   console.log("Start preparing cheese with " + milk);
   setTimeout( function() {
      console.log("Done preparing cheese.");
      callbackWhenCheeseIsAvailable(null, "CHEESE");
   }, 3000);
};
```

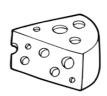

```
function sellCheese( cheese, callbackWhenCheeseHasBeenSold ) {
   console.log("Start selling " + cheese);
   setTimeout( function() {
      console.log("Done selling " + cheese);
      callbackWhenCheeseHasBeenSold(null, "MONEY");
   }, 1000);
};
```

```
heig-vol
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud
```

```
milkCow( function(err, milk) {
    console.log("I have " + milk + " and can prepare cheese.");
    prepareCheese(milk, function(err, cheese) {
        console.log("I have now " + cheese + " and can sell it.");
        sellCheese(cheese, function(err, money) {
            console.log("Youpi! I have my money.");
        });
    });
});
```

```
$ node promise.js
Start to milk cow...
Done milking cow.
I have now some MILK and can prepare cheese.
Start preparing cheese with MILK
Done preparing cheese.
I have now CHEESE and can sell it.
Start selling CHEESE
Done selling CHEESE
Youpi! I have my money.
```

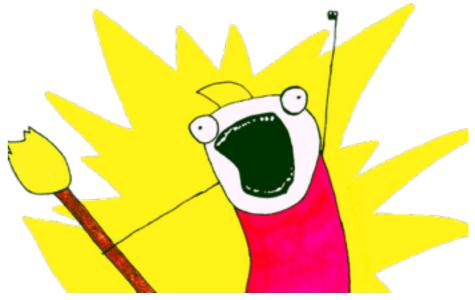

```
heig-vol
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud
```

```
milkCow( function(err, milk) {
   console.log("I have " + milk + " and can prepare cheese.");
   prepareCheese(milk, function(err, cheese) {
      console.log("I have now " + cheese + " and can sell it.");
      sellCheese(cheese, function(err, money) {
       console.log("Youpi! I have my money.");
    });
});
});
```

At every level, you will have more than one line of code. It will quickly become difficult to know where you are...
Understanding and maintaining the code will be a nightmare.

First approach: use the async.js module

waterfall(tasks, [callback])

Runs the tasks array of functions in series, each passing their results to the next in the array.

However, if any of the tasks pass an error to their own callback, the next function is not executed, and the main callback is immediately called with the error.

Arguments

- tasks An array of functions to run, each function is passed a callback(err, result1, result2,
 ...) it must call on completion. The first argument is an error (which can be null) and any
 further arguments will be passed as arguments in order to the next task.
- callback(err, [results]) An optional callback to run once all the functions have completed.
 This will be passed the results of the last task's callback.

Example

```
async.waterfall([
   function(callback) {
      callback(null, 'one', 'two');
   },
   function(arg1, arg2, callback) {
      // arg1 now equals 'one' and arg2 now equals 'two'
      callback(null, 'three');
   },
   function(arg1, callback) {
      // arg1 now equals 'three'
      callback(null, 'done');
   }
], function (err, 'result) {
      // result now equals 'done'
});
```

The functions that we pass to async.waterfall must **respect a certain contract**:

the last parameter must be callback function (it will be provided by async.js and handle the magic)

the function must invoke this callback when it has completed

it must pass an error (if any) and **the**results it wishes to pass to the next
function.

the function must **declare parameters for the inputs** it wishes to receive from the previous function.

We are lucky!!!!

```
function prepareCheese( milk, callbackWhenCheeseIsAvailable ) {
   console.log("Start preparing cheese with " + milk);
   setTimeout( function() {
      console.log("Done preparing cheese.");
      callbackWhenCheeseIsAvailable(null, "CHEESE");
   }, 3000);
};
```

The functions that we pass to async.waterfall must respect a certain contract:

the last parameter must be callback function (it will be provided by async.js and handle the magic)

the function must invoke this callback when it has completed

it must pass an error (if any) and the results it wishes to pass to the next function.

the function must declare parameters for the inputs it wishes to receive from the previous function.

We can rewrite this...

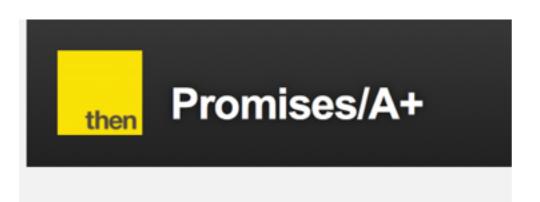

```
milkCow( function(err, milk) {
    console.log("I have " + milk + " and can prepare cheese.");
    prepareCheese(milk, function(err, cheese) {
        console.log("I have now " + cheese + " and can sell it.");
        sellCheese(cheese, function(err, money) {
            console.log("Youpi! I have my money.");
        });
    });
});
```

Into this...

```
async.waterfall([milkCow, prepareCheese, sellCheese],
function(err, results) {
   console.log("I have done all the work and now I have " + results);
});
```

- Async.js is one of the libraries that can help us with asynchronous code.
- There is a more general mechanism: promises.

An open standard for sound, interoperable JavaScript promises—by implementers, for implementers.

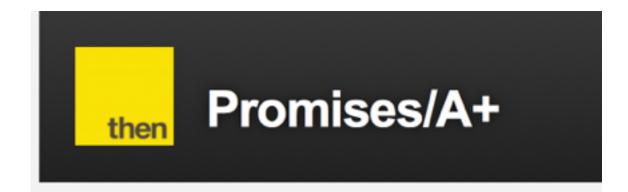

A promise represents the eventual result of an asynchronous operation. The primary way of interacting with a promise is through its then method, which registers callbacks to receive either a promise's eventual value or the reason why the promise cannot be fulfilled.

Deferred objects

- "A promise must be in one of three states: pending, fulfilled, or rejected.
- When **pending**, a promise:
 - may transition to either the fulfilled or rejected state.
- When **fulfilled**, a promise:
 - must not transition to any other state.
 - must have a value, which must not change.
- When **rejected**, a promise:
 - must not transition to any other state.
 - must have a reason, which must not change."

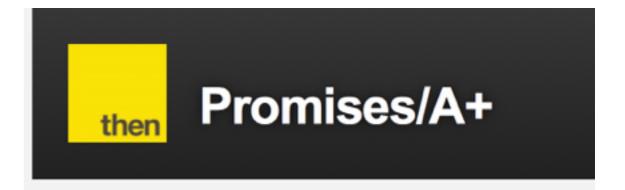

An open standard for sound, interoperable JavaScript promises—by implementers, for implementers.

A *promise* represents the eventual result of an asynchronous operation. The primary way of interacting with a promise is through its then method, which registers callbacks to receive either a promise's eventual value or the reason why the promise cannot be fulfilled.

https://github.com/promises-aplus/promises-spec

- "A promise must provide a then method to access its current or eventual value or reason.
- A promise's then method accepts two arguments:
 - promise.then(onFullfilled, onRejected)
- If onFulfilled is a function:
 - it must be **called after promise is fulfilled**, with promise's value as its first argument.
 - it must not be called before promise is fulfilled.
 - it must not be called more than once.
- If onRejected is a function,
 - it must be called after promise is rejected,
 with promise's reason as its first argument.
 - it must not be called before promise is rejected.
 - it must not be called more than once"

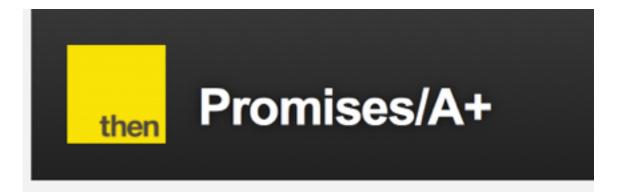

An open standard for sound, interoperable JavaScript promises—by implementers, for implementers.

A *promise* represents the eventual result of an asynchronous operation. The primary way of interacting with a promise is through its then method, which registers callbacks to receive either a promise's eventual value or the reason why the promise cannot be fulfilled.

https://github.com/promises-aplus/promises-spec

- "then must return a promise [3.3].
 - promise2 =
 promise1.then(onFulfilled,
 onRejected);
- If either onFulfilled or onRejected returns a value x, run the Promise Resolution Procedure [[Resolve]](promise2, x).
- If either onFulfilled or onRejected throws an exception e, promise2 must be rejected with e as the reason.
- If onFulfilled is not a function and promise1 is fulfilled, promise2 must be fulfilled with the same value as promise1.
- If onRejected is not a function and promise1 is rejected, promise2 must be rejected with the same reason as promise1."

An open standard for sound, interoperable JavaScript promises—by implementers, for implementers.

A *promise* represents the eventual result of an asynchronous operation. The primary way of interacting with a promise is through its then method, which registers callbacks to receive either a promise's eventual value or the reason why the promise cannot be fulfilled.

https://github.com/promises-aplus/promises-spec

Example 1: Deferred objects in JQuery

```
var d1 = new $.Deferred();
var d2 = new $.Deferred();
$.when( d1, d2 ).done(function ( v1, v2 ) {
   console.log( v1 ); // "Fish"
   console.log( v2 ); // "Pizza"
});
d1.resolve( "Fish" );
d2.resolve( "Pizza" );
```

"a **promise** represents a value that is not yet known a **deferred** represents work that is not yet finished"

http://blog.mediumequalsmessage.com/promise-deferred-objectsin-javascript-pt1-theory-and-semantics

https://api.jquery.com/jquery.when/

```
$.when( $.ajax( "/page1.php" ), $.ajax( "/page2.php" ) )
.then( myFunc, myFailure );
```

```
$.when( $.ajax( "/page1.php" ), $.ajax( "/page2.php" ) )
.done( function( a1, a2 ) {
   // a1 and a2 are arguments resolved for the page1 and page2 ajax requests, respectively.
   // Each argument is an array with the following structure: [ data, statusText, jqXHR ]
   var data = a1[ 0 ] + a2[ 0 ]; // a1[ 0 ] = "Whip", a2[ 0 ] = " It"
   if ( /Whip It/.test( data ) ) {
     alert( "We got what we came for!" );
   }
});
```

Example 2: Promises with Q

```
heig-vol
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud
```

```
function waitForGreetings1() {
    var deferred = Q.defer();
    setTimeout(function() {
        deferred.resolve("hello ");
    }, 2000);
    return deferred.promise;
};
```

```
function waitForGreetings2( previousResult ) {
    var deferred = Q.defer();
    setTimeout(function() {
        deferred.resolve(previousResult + "how are ");
    }, 200);
    return deferred.promise;
};
```

```
function waitForGreetings3( previousResult) {
    var deferred = Q.defer();
    setTimeout(function() {
        deferred.resolve(previousResult + "you?");
    }, 10);
    return deferred.promise;
};
```

These are 3 **asynchronous** operations

We **immediately** return the promise of a **future** result

Some of them expect an **input**

And produce an output

Example 2: Promises with Q

```
heig-vd

Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud
```

```
function waitForGreetings1() {
    var deferred = Q.defer();
    setTimeout(function() {
        deferred.resolve("hello ");
    }, 2000);
    return deferred.promise;
};
```

```
function waitForGreetings2( previousResult ) {
    var deferred = Q.defer();
    setTimeout(function() {
         deferred.resolve(previousResult + "how are "
    }, 200);
    return deferred.promise;
};
```

```
function waitForGreetings3( previousResult) {
    var deferred = Q.defer();
    setTimeout(function() {
         deferred.resolve(previousResult + "you?");
    }, 10);
    return deferred.promise;
};
```

We pass a function object (we don't invoke the function ourselves).

The function that we pass returns a promise.

```
waitForGreetings1()
   .then ( waitForGreetings2 )
   .then ( waitForGreetings3 )
   .then ( function(result) {
     console.log("final result : " + result);
});
```

When the promise returned by waitForGreetings1 is resolved, waitForGreetings2 is invoked (the result returned by waitForGreetings1 is passed in parameter)

Going back to our cheese problem...

We would like to rewrite this...

```
milkCow( function(err, milk) {
    console.log("I have " + milk + " and can prepare cheese.");
    prepareCheese(milk, function(err, cheese) {
        console.log("I have now " + cheese + " and can sell it.");
        sellCheese(cheese, function(err, money) {
            console.log("Youpi! I have my money.");
        });
    });
});
```

Into something like...

```
milkCow().then(prepareCheese).then(sellCheese).then(function() {...});
```

But our existing methods use callbacks, not promises...

Going back to our cheese problem...

- Bluebird is one of the most popular Promise libraries.
- It makes it possible to "promisify" existing functions:

```
var milkCowPromisified = Promise.promisify(milkCow);
var prepareCheesePromisified = Promise.promisify(prepareCheese);
var sellCheesePromisified = Promise.promisify(sellCheese);
```

```
milkCowPromisified()
   .then(prepareCheesePromisified)
   .then(sellCheesePromisified)
   .then( function( result ) {
     console.log("Final result: " + result);
    }
   );
```

Document-oriented NoSQL Database

MongoDB

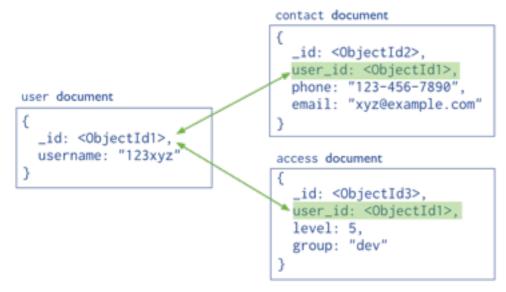

- MongoDB is one of the most popular NoSQL databases (and one of the first to have been categorized as such).
- It is a schema-less document-oriented database:
 - The data store is made of several collections.
 - Every collection contains a set of **documents**, which you can think of as JSON objects.
 - The structure of documents is not defined a priori and is not enforced.
 This means that a collection can contain documents that have different fields.

Collection

Data modeling

- Creating a data model with MongoDB does not have to follow the rules that apply for relational databases. Often, they should not.
- Consider theses questions: is this a composition relationship (containment)? Is this "aggregate" of documents often used at the same time (i.e. can we reduce chattiness)? Would embedding lead to "a lot" of data duplication?

Normalized data model

(references)

Embedded data model

(sub-documents)

One-to-one relationships

```
2 documents (requires 2 queries
                       to get all of the person data)
                                                                      1 single, aggregate document
_id: "joe",
                                        _id: "joe",
name: "Joe Bookreader"
                                                                     (in this case, it is a better choice)
                                        name: "Joe Bookreader",
                                        address: {
                                                   street: "123 Fake Street",
                                                   city: "Faketon",
patron_id: "joe",
                                                   state: "MA",
street: "123 Fake Street"
                                                   zip: "12345"
city: "Faketon",
state: "MA",
zip: "12345"
```

better if you have many books per publisher

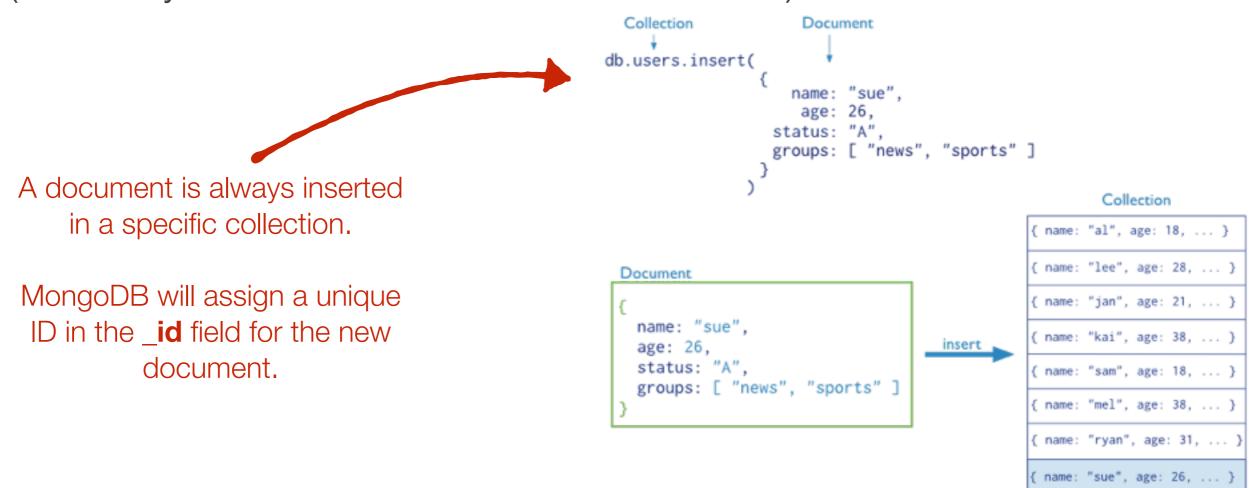

https://docs.mongodb.org/manual/tutorial/model-embedded-one-to-manyrelationships-between-documents/

Insert data in MongoDB

users

- To insert data in MongoDB, you simply have to provide a JSON document (with an arbitrary structure).
- The documents in the collection do not have to all have the same structure (this is why we talk about a **schemaless** database).

Insert data in MongoDB

• This is one example. You can also insert multiple documents at the same time, either by passing an array of documents or by performing a bulk operation. If you are dealing with many documents, this is important for

performance reasons.

Update and delete data in MongoDB

- When you update or delete documents, you specify which documents are concerned by the operation.
- You do that by specifying update or remove criteria. Specifying "{}" means that you want to apply the operation on all documents of the collection.

Update data in MongoDB

 By default, update will modify only the first document that matches the selection criteria. You can specify the "multi" options if you want to update all documents that match the criteria.

update operators

lastiviodified will be set to the current date

Update data in MongoDB

Update Operators

Fields

Name	Description
\$inc	Increments the value of the field by the specified amount.
\$mul	Multiplies the value of the field by the specified amount.
\$rename	Renames a field.
\$setOnInsert	Sets the value of a field if an update results in an insert of a document. Has no effect on update operations that modify existing documents.
\$set	Sets the value of a field in a document.
\$unset	Removes the specified field from a document.
\$min	Only updates the field if the specified value is less than the existing field value.
\$max	Only updates the field if the specified value is greater than the existing field value.
\$currentDate	Sets the value of a field to current date, either as a Date or a Timestamp.

Array

Operators

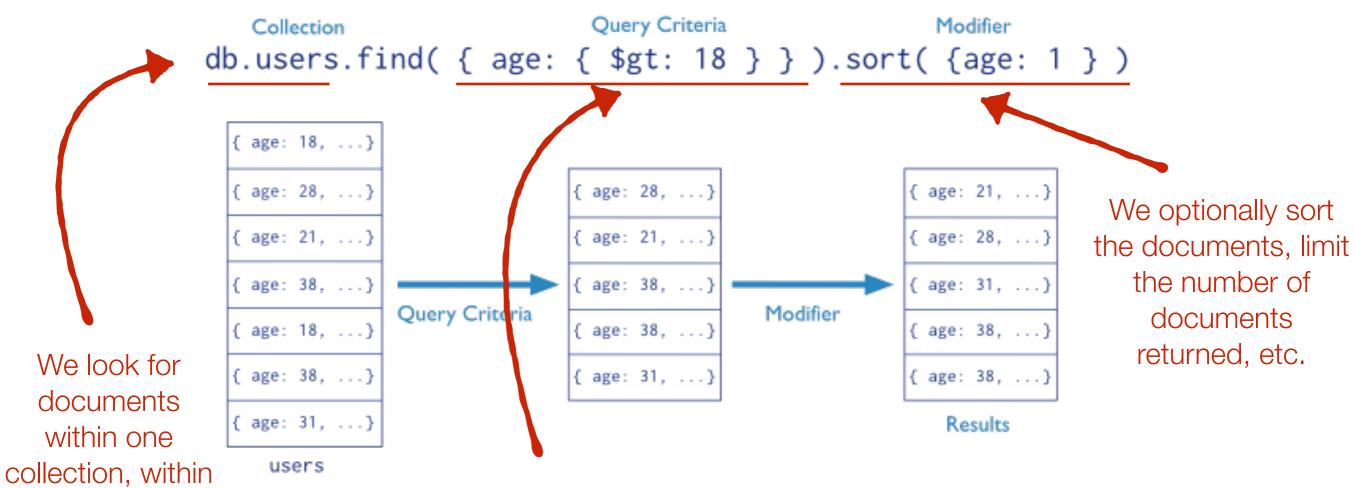

Name	Description
\$	Acts as a placeholder to update the first element that matches the query condition in an update.
\$addToSet	Adds elements to an array only if they do not already exist in the set.
\$pop	Removes the first or last item of an array.
\$pullAll	Removes all matching values from an array.
\$pull	Removes all array elements that match a specified query.
\$pushAll	Deprecated. Adds several items to an array.
\$push	Adds an item to an array.

Query MongoDB

one database

 MongoDB is one of the most popular NoSQL databases (and one of the first to have been categorized as such).

We define the criteria for which documents should be considered, and which of their fields should be considered (projection)

https://docs.mongodb.org/manual/core/crud-introduction/

Query MongoDB

```
db.inventory.find()

db.inventory.find( { type: "snacks" } )
```

all documents

documents, which have a field "type" with a value of "snacks"

```
db.inventory.find( { type: { $in: [ 'food', 'snacks' ] } } )
```

documents, which have a field "type" with have a value of "food" or "snacks"

```
db.inventory.find( { type: 'food', price: { $lt: 9.95 } } )
```

documents with a type field equal to "food" AND a price field with a value less than 9.95

```
db.inventory.find(
     {
          $or: [ { qty: { $gt: 100 } }, { price: { $lt: 9.95 } } ]
      }
)
```

documents where the quantity is more than 100 OR the price is less than 9.95

https://docs.mongodb.org/manual/tutorial/query-documents/

Query MongoDB: arrays

```
heig-vol
Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud
```

```
{ _id: 5, type: "food", item: "aaa", ratings: [ 5, 8, 9 ] }
{ _id: 6, type: "food", item: "bbb", ratings: [ 5, 9 ] }
{ _id: 7, type: "food", item: "ccc", ratings: [ 9, 5, 8 ] }
```

Exact match on the entire array

Return documents if the array contains a specific value

Query MongoDB: arrays

```
heig-vd

Haute Ecole d'Ingénierie et de Gestion
du Canton de Vaud
```

```
{ _id: 5, type: "food", item: "aaa", ratings: [ 5, 8, 9 ] }
{ _id: 6, type: "food", item: "bbb", ratings: [ 5, 9 ] }
{ _id: 7, type: "food", item: "ccc", ratings: [ 9, 5, 8 ] }
```

```
db.inventory.find( { ratings: { $elemMatch: { $gt: 5, $lt: 9 } } )
```

Documents where one element of ratings is at the same time > 5 AND < 9

```
{ "_id" : 5, "type" : "food", "item" : "aaa", "ratings" : [ 5, 8, 9 ] } { "_id" : 7, "type" : "food", "item" : "ccc", "ratings" : [ 9, 5, 8 ] }
```

```
db.inventory.find( { ratings: { $gt: 5, $lt: 9 } } )
```

Documents where there is one element of ratings > 5 and one element < 9

```
{ "_id" : 5, "type" : "food", "item" : "aaa", "ratings" : [ 5, 8, 9 ] }
{ "_id" : 6, "type" : "food", "item" : "bbb", "ratings" : [ 5, 9 ] }
{ "_id" : 7, "type" : "food", "item" : "ccc", "ratings" : [ 9, 5, 8 ] }
```

SQL vs MongoDB

```
heig-vd

Haute Ecole d'Ingénierie et de Gestion du Canton de Vaud
```

```
SELECT *
                               db.users.find(
                                                                       SELECT *
                                                                                                       db.users.find( { status: "A" } ).sort( { user_id: 1 } )
                                   { status: { $ne: "A" } }
FROM users
                                                                       FROM users
WHERE status != "A"
                                                                       WHERE status = "A"
                                                                       ORDER BY user_id ASC
SELECT *
                               db.users.find(
FROM users
                                   { status: "A",
                                                                                                       db.users.find( { status: "A" } ).sort( { user_id: -1 } )
                                                                       SELECT *
WHERE status = "A"
                                      age: 50 }
                                                                       FROM users
AND age = 50
                                                                       WHERE status = "A"
                                                                       ORDER BY user_id DESC
SELECT *
                               db.users.find(
FROM users
                                   { $or: [ { status: "A" } ,
                                                                                                       db.users.count()
                                                                       SELECT COUNT(*)
                                             { age: 50 } ] }
WHERE status = "A"
                                                                       FROM users
OR age = 50
                                                                                                       or
                               db.users.find(
SELECT *
                                                                                                       db.users.find().count()
FROM users
                                   { age: { $gt: 25 } }
                                                                                                       db.users.count( { user_id: { $exists: true } } )
WHERE age > 25
                                                                       SELECT COUNT(user_id)
                                                                       FROM users
SELECT *
                               db.users.find(
                                                                                                       or
                                  { age: { $lt: 25 } }
FROM users
WHERE age < 25
                                                                                                       db.users.find( { user_id: { $exists: true } } ).count()
SELECT *
                               db.users.find(
                                                                       SELECT COUNT(*)
                                                                                                       db.users.count( { age: { $gt: 30 } } )
                                  { age: { $gt: 25, $lte: 50 } }
FROM users
                                                                       FROM users
WHERE age > 25
                                                                       WHERE age > 30
                                                                                                       OF
AND age <= 50
                                                                                                       db.users.find( { age: { $gt: 30 } } ).count()
SELECT *
                               db.users.find( { user_id: /bc/ } )
FROM users
                                                                       SELECT DISTINCT(status)
                                                                                                       db.users.distinct( "status" )
WHERE user_id like "%bc%"
                                                                       FROM users
```

https://docs.mongodb.org/manual/reference/sql-comparison/

Query MongoDB: projections

• When you perform a query, you can specify which fields you are interested in (think about performance)

```
db.inventory.find( { type: 'food' } )
```

Return all fields (no second argument)

```
db.inventory.find( { type: 'food' }, { item: 1, qty: 1 } )
```

We are only interested by the item and qty fields (we will also get _id)

```
db.inventory.find( { type: 'food' }, { item: 1, qty: 1, _id:0 } )
```

We are only interested by the item and qty fields (we really don't want to get _id)

```
db.inventory.find( { type: 'food' }, { type:0 } )
```

https://docs.mongodb.org/manual/tutorial/ project-fields-from-query-results/

We want all fields except type

Accessing MongoDB from Node.js

Accessing mongoDB from Node.js

- In the **Java ecosystem**, it is possible to interact with a RDBMS by using a JDBC driver:
 - The program loads the driver.
 - The program establishes a connection with the DB.
 - The program sends SQL queries to read and/or update the DB.
 - The program manipulates tabular result sets returned by the driver.
- With Node.js and mongoDB, the process is similar:
 - There is a Node.js driver for mongoDB (in fact, there are several).
 - A Node.js module can connect to a mongoDB server and issue queries to manipulate collection and documents.

Example 1: connect and insert

```
var MongoClient = require('mongodb').MongoClient;
MongoClient.connect("mongodb://localhost:27017/exampleDb", function(err, db) {
  if(err) { return console.dir(err); }
  var collection = db.collection('test');
  var doc1 = {'hello':'doc1'};
  var doc2 = {'hello':'doc2'};
  var lotsOfDocs = [{'hello':'doc3'}, {'hello':'doc4'}];
  collection.insert(doc1);
  collection.insert(doc2, {w:1}, function(err, result) {});
  collection.insert(lotsOfDocs, {w:1}, function(err, result) {});
});
```

Example 2: query

```
var MongoClient = require('mongodb').MongoClient;
MongoClient.connect("mongodb://localhost:27017/exampleDb", function(err, db) {
  if(err) { return console.dir(err); }
  var collection = db.collection('test');
  var docs = [{mykey:1}, {mykey:2}, {mykey:3}];
  collection.insert(docs, {w:1}, function(err, result) {
    // beware of memory consumption!
    collection.find().toArray(function(err, items) {});
    // better when many documents are returned
    var stream = collection.find({mykey:{$ne:2}}).stream();
    stream.on("data", function(item) {});
    stream.on("end", function() {});
    // special case when only one document is expected
    collection.findOne({mykey:1}, function(err, item) {});
 });
```

Accessing mongoDB from Node.js

 mongojs is a very useful npm module, which provides an alternative to the official Node.js driver. Its API is very similar to what you type on the mongo

```
// simple usage for a local db
var db = mongojs('mydb', ['mycollection']);

// the db is on a remote server (the port default to mongo)
var db = mongojs('example.com/mydb', ['mycollection']);

// we can also provide some credentials
var db = mongojs('username:password@example.com/mydb', ['mycollection']);

// connect now, and worry about collections later
var db = mongojs('mydb');
var mycollection = db.collection('mycollection');
```

```
// find everything
db.mycollection.find(function(err, docs) {
    // docs is an array of all the documents in mycollection
});

// find everything, but sort by name
db.mycollection.find().sort({name:1}, function(err, docs) {
    // docs is now a sorted array
});
```

Haute Ecole d'Ingénierie et de Gestion du Canton de Vaud

Let's celebrate October!

Phase 2

Instead of storing beers in local files, can we store them in MongoDB?

- Instead of storing beers in local files, can we store them in MongoDB?
 - How can talk to MongoDB from my Node.js script?
 - If I have a JavaScript beer object, what do I need to pass to MongoDB?
 - How do I handle duplicates (the API gives me a random beer, so it is possible to get the same beer more than once)."
 - Once I have beers in MongoDB, how can I query the data?

How can talk to MongoDB from my Node.js script?

- There are many different ways. Some of the options are listed on the MongoDB site: http://docs.mongodb.org/ecosystem/drivers/node-js/
- We will **not** use the officially supported driver here. Instead, we will first use the **mongojs** node module, which provides an API very similar to what you type on the mongo interactive shell (so it's pretty cool if you are getting started with MongoDB).
- Later on, we will use the Mongoose mapping framework, which provides a higher-level API (a bit like JPA offers a higher-level API than JDBC in the Java EE ecosystem).

- How can talk to MongoDB from my Node.js script?
 - Lets create another file (we will transform it into a Node.js module later on, but for now we only want to be able to test the DB stuff separtely).
 - Let's also install the mongojs module.

```
touch mokto.js
npm install --save mongojs
```

 If we don't worry about the entire sequence of operations right now, we can try to connect to the local database and insert a document in a collection.

```
var mongojs = require('mongojs');
var db = mongojs('beersDb', ['beers']);
db.beers.insert( { "name" : "boxer", "country" : "Switzerland"}, function(err, document) {});
```

How can talk to MongoDB from my Node.js script?

 We want to close the DB connection, but we have to be careful not to do it before or while we are inserting. So at the moment, we need to do it in the callback function.

```
debugger; // that will make it easy to use "slc debug mokto.js ."

// We connect to the local server and use the beersDb database, and the beers collection

// If they don't exist, they will be created on the fly

var db = mongojs('beersDb', ['beers']);

db.beers.insert( { "name" : "boxer", "country" : "Switzerland"}, function(err, document) {
    if (err) {
        console.log("Error while inserting document " + err.errmsg);
    } else {
        console.log("Document created with _id : " + document._id)
    }
    console.log("We know that the insert has been done, so it is safe to close the DB connection.")

    db.close();

});

// if we were doing db.close() here, we would close the connection too early!
```

How can we insert documents from a MongoDB collection?

```
function insertBeer( beer, callbackWhenBeerHasBeenInserted ) {
   var db = mongojs('beersDb', ['beers']);
   db.beers.insert( beer, function(err, doc) {
        db.close();
        if (err) {
            console.log("Unable to insert beer: " + beer);
            callbackWhenBeerHasBeenInserted(err);
        } else {
            console.log("Beer has been inserted: " + beer);
            callbackWhenBeerHasBeenInserted(null, doc);
        }
    });
}
```

- How do we create a module, export functionality and import it?
- In your module (mokto.js), use module.exports

```
function insertBeer( beer, callbackWhenBeerHasBeenInserted ) {
...
}

var beerDB = {
    insertBeer: insertBeer
}

module.exports = beerDB;
```

• In the client module (okto.js), import the module:

```
var database = require("./mokto.js");
function saveBeerInMongo(beer, callback) {
    database.insertBeer(beer, function(err, doc) {
        if (err) throw err;
        console.log("Beer has been saved in MongoDB with id " + doc._id);
        callback(null , doc);
    });
}
```

Object Document Mapping with Mongoose

Mongoose: an ORM for MongoDB

- In the **Java EE ecosystem**, we have seen how the **Java Persistence API** (JPA) specifies a standard way to interact with Object-Relational Mapping (ORM) frameworks.
 - The developer first creates an object-oriented domain model, by creating Entity classes and using various annotations (@Entity, @Id, @OneToMany, @Table, etc.)
 - He then uses an Entity Manager to Create, Read, Update and Delete objects in the DB.
 - The ORM framework takes care of the details: it generates the schema and the SQL queries.
- In the Javascript ecosystem, we have similar mechanisms. With the particular yeoman generator that we use for the project:
 - The authors have decided not use a relational database, but rather the mongodb documentoriented database.
 - They have decided to use **one of the data mapping tools** available for mongodb, namely **mongoose**. Since mongodb is a document-oriented database, it is more appropriate to talk about an Object-Document Mapping tool, rather than an ORM.

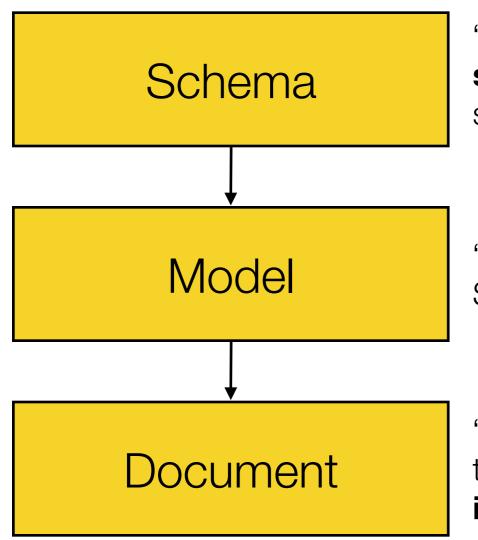

Why is not completely correct to say that mongoose is an ORM for MongoDB?

Mongoose: an ODM for MongoDB

"Mongoose provides a **straight-forward**, schema-based solution to **modeling** your application data and includes built-in type **casting**, **validation**, **query** building, business logic hooks and more, out of the box."

"Everything in Mongoose starts with a Schema. Each schema maps to a MongoDB collection and defines the shape of the documents within that collection."

"Models are fancy constructors compiled from our Schema definitions."

"Mongoose documents represent a **one-to-one mapping** to documents as stored in MongoDB. Each document is an **instance of its Model**."

http://mongoosejs.com/docs/guide.html

```
schema
                                                                heig-vd
Example
                                                                Haute Ecole d'Ingénierie et de Gestion
                                                                du Canton de Vaud
                                          collection
                        model
var userSchema = new mongoose.Schema({
  name: {
    first: String,
    last: { type:/String, trim: true }
  age: { type:/Number, min: 0 }
});
var PUser = mongoose.model('PowerUsers', userSchema);
var johndoe = new PUser ({
  name: { first: 'John', last: 'Doe'},
  age: 25
});
johndoe.save(function (err) {if (err) console.log ('Error on save!')});
                       document
```

https://devcenter.heroku.com/articles/nodejs-mongoose

Example: query

we can chain conditions

```
Person
.find({ occupation: /host/ })
.where('name.last').equals('Ghost')
.where('age').gt(17).lt(66)
.where('likes').in(['vaporizing', 'talking'])
.limit(10)
.sort('-occupation')
.select('name occupation')
.exec(callback);
```

we are interested in only some of the fields

we only want to get at most 10 documents

http://mongoosejs.com/docs/queries.html

Yo express!

yo angular

```
// Example model
var mongoose = require('mongoose'),
  Schema = mongoose.Schema;
var ArticleSchema = new Schema({
  title: String,
  url: String,
  text: String
});
ArticleSchema.virtual('date')
  .get(function(){
    return this._id.getTimestamp();
  });
mongoose.model('Article', ArticleSchema);
```

app/models/article.js

yo angular

```
var express = require('express'),
  router = express.Router(),
  mongoose = require('mongoose'),
  Article = mongoose.model('Article');
module.exports = function (app) {
  app.use('/', router);
};
router.get('/', function (req, res, next) {
  Article.find(function (err, articles) {
    if (err) return next(err);
    res.render('index', {
      title: 'Generator-Express MVC',
      articles: articles
   });
  });
```

app/controllers/home.js

Yo angular-fullstack!

```
yo angular-fullstack
```

```
'use strict';

var mongoose = require('mongoose'),
    Schema = mongoose.Schema;

var ThingSchema = new Schema({
    name: String,
    info: String,
    active: Boolean
});

module.exports = mongoose.model('Thing', ThingSchema);
```

du Canton de Vaud

Yo angular-fullstack!

```
'use strict';
var = require('lodash');
var Thing = require('./thing.model');
// Get list of things
exports.index = function(req, res) {
  Thing.find(function (err, things) {
    if(err) { return handleError(res, err); }
    return res.json(200, things);
 });
// Get a single thing
exports.show = function(req, res) {
  Thing.findById(req.params.id, function (err, thing) {
    if(err) { return handleError(res, err); }
    if(!thing) { return res.send(404); }
    return res.json(thing);
```

```
// Updates an existing thing in the DB.
exports.update = function(req, res) {
  if(req.body._id) { delete req.body._id; }
 Thing.findById(req.params.id, function (err, thing) {
    if (err) { return handleError(res, err); }
    if(!thing) { return res.send(404); }
   var updated = .merge(thing, req.body);
    updated.save(function (err) {
      if (err) { return handleError(res, err); }
      return res.json(200, thing);
   });
 });
// Deletes a thing from the DB.
exports.destroy = function(req, res) {
 Thing.findById(req.params.id, function (err, thing) {
    if(err) { return handleError(res, err); }
    if(!thing) { return res.send(404); }
   thing.remove(function(err) {
      if(err) { return handleError(res, err); }
      return res.send(204);
   });
  });
```

yo angular-fullstack

```
'use strict';
var express = require('express');
var controller = require('./thing.controller');
var router = express.Router();
router.get('/', controller.index);
router.get('/:id', controller.show);
router.post('/', controller.create);
router.put('/:id', controller.update);
router.patch('/:id', controller.update);
router.delete('/:id', controller.destroy);
module.exports = router;
```
